Dear Dr. Cho,

Thank you for the invitation to revise and resubmit our manuscript. In this and the previous re-submission, we have expended significant efforts to address all the concerns of the three reviewers, to the extent of modifying our algorithm and reprocessing and re-analyzing hundreds of datasets.

We are heartened that Reviewers #1 and #3 endorsed our manuscript for publication in Nature Communications. However, we are rather surprised by Reviewer #2's continued criticisms. Fundamentally, we feel that the remaining criticisms represents relatively minor sources of bias in these data. Nonetheless, we have tried to do all potential calculations to address the criticism -- involving many month-long computes. We demonstrate in our response and manuscript that the effects he or she claims are largely inconsequential to the results we report in our piece. Moreover, Reviewer #2's comments suggest that there is a universally accepted standard for reporting allelic effects, which is simply not the case and we hope to make this clear in this letter and in the response.

Now in detail, Reviewer #2 had cited two major concerns in both rounds of reviews: (a) mapping and (b) overdispersion in the datasets.

For (a), as also explained in our current response to the reviewer, the allelic differences in mapping, or 'allelic mapping bias', includes the reference bias, which we have already accounted for by the use of diploid personal genomes. Various studies have a different take on how to account for the bias (Supplementary Table 1), with many agreeing that the alignment to a personal genome, as we have done here, is a conservative and effective method for mitigating a large amount of potentially confounding bias [1, 2, 3].

Nonetheless, in this round of revision, we have strived to quantify and compensate for the bias highlighted by Reviewer #2, which we termed the 'ambiguous mapping bias' [1,4]. We show that the ambiguous mapping bias has a smaller effect than the reference bias and does not change the main results of our previous submission. Thus, we interpreted Reviewer #2's comment as asking us to add in a small bias correction filter in order to make our approach fully compliant

with what he or she sees as the standard for the field. While small, this addition actually required many month-long re-computes to reprocess all the 1,263 datasets in a uniform fashion. Moreover, our approach actually exceeds this level of correction since it accounts for additional issues, such as reference bias correction, better read alignment and the ability to incorporate variants beyond just SNVs, e.g. indels (as shown by Sudmant *et al.*) [5].

For (b), in his previous comments, he mentioned that “the correct analysis must use *some* strategy to estimate the *overdispersion* parameter and take it into account when testing for ASE”. Based on just this very general description, we first responded by explaining that there is *indeed* a range of *perspectives and methods* to account for the issue of *overdispersion* [4,6-9] (please also refer to *Supplementary Table 1*). We then went to great lengths to implement a novel two-step procedure to account for overdispersion in the context of our approach. In response, he commented that the previous methods were “mistakes” and that they “got it wrong”. We would like to point out that these methods are *some* of the *most current work by authorities and peer-reviewed* by colleagues in the *field*. More importantly, the key point that we are trying to make is *not* to show the ‘correctness’ of these methods, but to point to the broader reality that there is currently a diversity of methods in the community. For example, Castel *et al.* from *Genome Biology* [1] describes a new tool in the GATK software package and discussed the best practices for allele-specific analyses that do *not* take overdispersion into account. Van de Geijn *et al.* from *Nature Methods* [4] introduced a new allele-specific detection tool that takes into account overdispersion on a per-individual basis (similar to our pipeline; not site-specific as suggested by Reviewer #2).

Given the plurality of current approaches, the fact that the reviewer has been insisting on his/her points of view suggests his/her prejudice for a particular ‘right’ approach, when there is simply no firm consensus. Furthermore, our current approach has already been extensively discussed and utilized in the ENCODE [10], and the Epigenomics Roadmap consortia. It has also been implemented in the recent *Nature* publication by the 1000 Genomes Project Structural Variants (SV) group [5], which was the reason we initially submitted this manuscript as a companion to the 1000 Genomes paper, as the methods were extensively used by the consortium, particularly in the SV and Functional Interpretation groups.

We have made considerable efforts to modify our manuscript to take into account Reviewer #2’s criticisms while preserving the main themes of our manuscript. We are deeply encouraged by the other two reviewers’ endorsements of our current manuscript and indeed strongly believe that our approach and resource will generate considerable interest in the community. Hence, we do hope to seek your understanding and consideration of this cover letter when making your decision.

Yours sincerely,

Mark Gerstein

Albert L. Williams Professor of Biomedical Informatics,  
Co-director of the Yale Program in Computational Biology and Bioinformatics  
Co-chair of 1000 Genomes Project Consortium Functional Interpretation Group
