Referee Comment	The referees have raised a range of technical concerns on the analyses, including for the background mutation rate, the need to include statistical significance to support many of the claims, and the limitations of this data including cell lines used.		Formatted Table
Author Response	We've tried to respond to extensively revise our manuscript in our new version. In summary, we've answered most of these comments. We felt many of these were good suggestions, so we expanded on them in large conserving the manuscript, particularly the suggestion related to SVs statistics on networks and SUB1.		Moved (insertion) [1]
	One area that we wish to push back a little on is asking us to compare our calculations to that for driver identification. The point of this paper is not to develop a novel method of driver discovery or to find new cancer drivers. The point is to highlight the use of ENCODE data in cancer genomics, particularly related to understand the overall patterns of mutations, network rewiring, and variant prioritization. Obviously, the ENCODE data will be useful for people developing future driver discovery metrics but we believe that's out of scope for this paper. To respond to previous comments, we've shown how in certain contexts, the ENCODE date can help with existing driver discovery measures.		Formatted: Font:Helvetica Neue Deleted: (JZ2MG: this is to the editor, not to referees, but still can be seen by referees, how much detail should we go to)

-- Editor 0.3 – Overall comments on the paper --

\$\$\$Presentation @@@MG @@@JZ&&&compl

Referee Comment	The referees also recommended that the current manuscript does not represent a distinct advance to the main ENCODE manuscript, as it does not report separate new datasets, methods, or clear novel findings. Some referees also recommended that this may be more suitable as Perspective in a specialized journal that further highlights the use on the current ENCODE datasets for cancer genomic studies.	Formatted Table
Author Response	We disagree with the reviewers on this point. We want to make it explicit that (1) this paper is to be considered as a "resource" paper, not a novel biology paper (2) that the current Encyclopedia package is not meant to be structured like previous packages (i.e. '12 ENCODE). The integrative analysis is meant to be spread over a number of papers and not centered on a single one. (3) note that the ENCODE 3 "data" is not explicitly tied to any paper. Unlike previous roll-outs, ENCODE 3 does not associate particular data sets with specific papers and make use of these data contingent on that paper's publication (as codified in an agreement with NHGRI.) Regarding the novelty of this paper, ENCODEC is unique in its highlighting of a number of ENCODE assays (e.g. replication timing, TF knockdowns, STARR-seq and Hi-C), its deep, integrative annotations combining a wide variety of assays in specific cell types, and its analysis of networks. Note also that while we do NOT feel ENCODEC is a cancer genomics paper, we feel that cancer is the best application to illustrate certain key aspects of ENCODE data and analysis - particularly deep annotations and network changes. We have listed some more details about novelty of this paper as below.	Deleted: (Core of the argument) ([1

	(1) Networks. These are a core aspect of ENCODE, featured in the '12 roll out. None of the other papers highlight networks in the current package. In ENCODEC,		
	in addition to looking at "universal ChIP-Seq networks, merged across cell types, we also look at network changes ("rewiring") for specific cell-type comparisons.		
	We feel that this is best exemplified in oncogenesis.		
	(2) Deep, integrative annotation – complementary to the Encyclopedia. While the encyclopedia paper considers broad, "universal" annotations across cell-		
	types (currently the centerpiece of ENCODE), it focuses on data common to most cell types (DHS, 2 histone marks and 2 TFs). It does not take advantage of the cell types richer in assays the other dimension of ENCODE (diagrammed in		
	ENCODEC's first figure). The ENCODEC paper takes a complementary approach, constructing a more accurate annotation using a large battery of histone marks (>10), next generation assays such as STARR-seq and elements linked by ChIA-		
	PET and Hi-C.		
	(3) Replication Timing. Although a major feature of ENCODE is replication timing, none of the other papers feature it. Previous work on mutation burden calculation usually selects replication timing data from the HeLa cell line due to the limited data availability. The wealth of the ENCODE replication timing data		
	greatly helps to parametrize somatic mutation rates.		
	(4) SVs. One unappreciated aspect of ENCODE is that next-generation assays, in addition to characterizing functional elements in the genome, enable one to		
	<u>determine structural variations.</u>(5) Knockdowns. ENCODE has 222 TF knockout/knockdown experiments, which are not explored systematically in other papers.		
	1		Deleted: We disagree with the reviewer with regarding the new dataset and novelty of this manuscript.

Referee #1 (Remarks to the Author):

-- Ref 1.1 – Overall comments on the paper --

\$\$\$NoveltyPos

Referee Comment	This manuscript describes how the ENCODE project data could- be utilized to derive insights for cancer genome analysis. It has several examples to illustrate this point, e.g., how to better estimate background mutation rate in a cancer genome, how to modify gene annotation for finding mutation-enriched regions (e.g., by bundling enhancer regions to target genes using Hi-C/ChIA-PET), and describing the changes in regulatory networks in cancer. Obviously, the ENCODE project involves a great deal of planning and a lot of experimental work by many groups, and the overall aim of re-highlighting the ENCODE as a resource to cancer research seems worthwhile in general, perhaps even in a high-profile journal.	Formatted Table
Author Response	We thank the referee for the positive feedback.	
Excerpt From Revised Manuscript

\$\$\$NoveltyNeg \$\$\$Text @@@JZ(@@@WM @@@MRS) &&&compl

Referee Comment	However, I find the current manuscript seriously lacking. The major problem is simply that most of these applications have already been in the literature for a while, often as high profile papers on their own. So the manuscript is not quite a review but does not seem to have any significant findings either.	Formatted Table
Author Response	We thank the reviewer for pointing out the existence of other literature that relates to the significant problems we address. We have summarized various references mentioned by the referees and made comparisons as below.

# \$\$\$BMR \$\$\$Text @@@WM @@@JZ @@@PDM&&&compl

Referee Comment	Just to take the first application as an example, the problem of estimating background somatic mutation rate accurately in order to better identify cancer drivers has been studied extensively in the literature. One paper, "Mutational heterogeneity in cancer and the search for new cancer- associated genes" (Nature 2013), is cited in the current manuscript, but there are many others. For instance, Weinhold et al, 2014 (Genome-wide analysis of noncoding regulatory mutations in cancer, Nat Genetics), Araya et al, 2015 (Identification of significantly mutated regions across cancer types highlights a rich landscape of functional molecular alterations, Nat Genetics), and similar non-coding mutation identification papers all include steps to account for epigenetic features in their background rate calculation.

١

We thank the reviewer for identifying these references. We recognize that epigenetic features have been previously been used to estimate BMR and improve driver mutation detection. Our aim was not to produce novel BMR estimation models, but rather to showcase how ENCODE data can help improve the performance of such models.

With the wealth data available through ENCODE data, we had a much larger pool of features to choose from to potentially improve BMR estimation. It is worth to mention that ENCODE data is not just cell line data, in fact XXX of this histone modification data is

	actually from real tissues. I Indeed, we found that application of some additional features from the this expansive set, especially the replication timing data, significantly improved BMR estimation in many cancer types (see Supplement Section S7).	
	In addition, were able to use cell-type matched feature data across our BMR analysis. This includes more commonly used features for BMR modification, like the 932 histone modification features we used, but also many other features, especially the 51 replication time data, that have proven useful but are less frequently incorporated into BMR models.	
	For example, many prior efforts to model BMR have been limited by the availability of genomic assays, or by the availability of assays matched by cell-type. For example, Lawrence et al., 2013, used HeLa replication timing data and K562 chromatin state via Hi-C. Martincorena et al., 2017, only included histone modification features, but not replication timing. The genomic signals we used from ENCODE have been processed uniformly and are provided in a ready-to-use format for the community.	
	We do not intend to claim it is a new discovery that using matched features are better, but rather to show that the breadth of ENCODE data allows for improved estimates of background mutation rate. We have further acknowledged prior efforts on this topic in our revised manuscript.	
Evernt	¥	Deleted: Admittedly we agree that this part is less novel compared to other sections. We have moved two related panels to the supplement and

#### \$\$\$BMR \$\$\$Text @@WM @@@JZ&&&compl

Referee Most large-scale cancer genome sequencing papers also have models at various levels sophistication, most of them Comment. including the issue of proper tissue-type matching. Importantly, Polak et al, 2015 (Cell-of-origin chromatin organization shapes the mutational landscape of cancer, Nature) in fact show that cell-of-origin chromatin features are much stronger determinants of cancer mutations profiles than chromatin feature of matched cancer cell lines, and that cell type origin can be predicted from the mutational profile. Thus, that "matched" cell lines are better than unmatched or addition of more epigenetic features results in some improvement is almost trivial at this point. Which marks contribute to this is also not new.

		$\prec$	
	Thanks for pointing out the Polak 2015 paper. (Note we did cite this in our manuscript.)	$\mathcal{D}$	)
	1. First we want to emphasize some specific type of data from ENCODE such as Hi-C and		
	replication timing. By pointing out that using data from a matched cell line is better, is not used as a novel conclusion (as we also cited the Polak 2015 paper), but rather to emphasize		
	the value of our data. Take replication timing as an example, a lot previous work <u>(lawrence</u> )	-	Deleted: ([jz cite])
	et al. 2013) actually use replication timing data from HeLa cell line due to the limited		Deleted: Hela
	choice. In our revised manuscript, we described that there are 51 high quality replication		Deleted: xxx
	timing data, which is quite valuable for cancer genomics. 2. Regarding the cell line data, we still think they are quite useful to predict the mutation-		
	rates. Two points need to note are:		
	(A) Even in the the Polak 2015 paper, it is not always the case that cell-of-origin can be		
	predicted perfectly using the epigenetic features (Fig. 4 b).		
	(B) the Polak 2015 paper only compare among normal tissues from the Roadmap data and		
	they did not compare cell line data at all.		

 Here we used breast cancer as an example to show the importance of cell line data. We calculated the correlation of breast cancer mutation counts (from a patient cohort) per mbp with histone signals from both Breast tissue (the roadmap) and MCF-7 (an ENCODE cell line). As seen from the following figure, MCF-7 provides similar (and sometimes even better correlation with mutation counts). We also found that histones from tissue and matched cell lines are actually quite correlated in a larger scale (see heatmap below).

#### \$\$\$BMR \$\$\$Calc @@@JZ&&&compl

2

Referee Comment	3) The approach with principal components used for the BMRe estimation does not seem to work well. Starting with the second PC most components have roughly the same prediction power. One possibility is that higher principle components do not capture the additional signal and reflect noise in the data, and the correlation with mutation rate is due to an overfit of the NB regression (it is unclear whether it was analyzed with cross-validation). Another possibility is that the signal is spread over many components. In the latter case, this is not an optimal method choice.	Formatted Table
Author Response	We thank the referees for understanding/agreeing with our point - a lot of data helps, <u>Actually</u> , PCs are not part of our model - it is just for the demonstration purpose. And we did not use it in our final BMR estimation. In the revised version, we actually used forward selection to show that adding more data will greatly help with the BMR prediction.	Deleted:

Referee 4) I do not agree with the power analysis presented to support. Formatted Table

	toy analysis neglecting specific properties of mutation rate known for regulatory regions and also sequence context dependence of mutation rate. The larger issue is that the analysis assumes that ALL functional sites are within the compact annotation. In that case, power indeed would decrease with length. However, in case some of the functional sites are outside the compact annotation power would not decrease and is even likely to increase with the inclusion of additional sequence. Is there a justification for all functional sites to reside within compact annotations? Can this issue be explored? Some statistical tests incorporate weighting schemes.	
Author Response	@@@@?mar - more & be positive - we've thoguth band we We thank the referee for accuration pointing out this present. The current power analysis,	
	which is also mentioned in previous literatures [[cite. Jz2add]] assumes that all the functional sites are within the test regions, is a fairly strong assumption and usually far away from the truth. In some cases, we do feel that the true functional sites might be allocated across various coding/noncoding elements. One example is the GATA3 case, there might be some mutational hotspots outside of the coding regions only. Some kind of	$\mathcal{F}$
	joint test might increase detection power.	100/76         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1         1
	Actually this is the reason why we are proposing testing the extended gene regions. To illustrate this concept, we added a whole section of new power analysis in our	Deleted:
	supplementary file to discuss cases when and how power can be increased by joint testing.

Referee Comment	Next, TF binding and nucleosome occupancy is known to interfere with the activity of DNA repair system.
Author Response	We thank the referee to bring out this important point. Actually many of the current background mutation rate estimation method assumes a constant rate in a fairly large region, such as a within a gene (including the long introns in between) or up to Mbp fixed bins. In such large scale, it is difficult to incorporate such as TF binding, nucleosome occupancy, histone modification (which changes sharply in less kbps). Hopefully, with accumulating cancer patient data in the future could help to build up site specific background models to investigate more about such effects. We added this point in our discussion section.

#### \$\$\$NoveltyPos&&&compl

\$\$110velly	rosaaacompi	
Referee Comment	I fully acknowledge that the manuscript proposes a very- important approach from detecting the mutations that are most relevant for each specific type of cancer, integrating epigenome data, transcription factor binding, chromatin looping to focus on key regions: ultimately, this work demonstrates the importance of functional data beyond the primary sequence of the genome. Other important aspects include the comprehensiveness and breadth of the data, the analysis and ultimately the whole integrated approach, which goes beyond commonly seen genomics analysis. However the manuscript is not trivial to read and digest in the first round: anyway I believe that the message, including the importance of the integration multiple types of data, is very important.	Formatted Table
Author Response	We thank the referee for the positive comments.

-- Ref 4.4 - Can you validate the cell line results using tissue data --

\$\$\$CellLine &&&More \$\$\$Calc @@@PE @@@DL @@@JZ @@@Peng&&&TBC

Referee	2) One of the limitations of the analysis are the cells that <b>Formatted Table</b>
Comment	are central in the ENCODE, that are immortalized, including
	cancer cells and "normal" immortalized counterparts. Most of

CODE these cell lines have been kept in culture for decades and further selected for cell growth very extensively. Many of the cell lines may have/have accumulated further mutation and rearrangements, if compared to what cancer cells are at the moment that they leave the human body. The authors accurately acknowledge, in the discussion, stating that it is difficult to match cancer cells with the right normal counterpart; it may also be even more difficult to define what are they really (I have seen data in other studies, showing that many of cancer cell transcriptome are quite similar to each other, if compared to initial or primary cells, showing that in particular cancer cells lose diversity). It would be appropriate to (computationally) verify at least small part of the data in other systems, taking from а published studies including normal cells control and primary cancers. Author Moved down [3]: Try to use some of the imputed stuff on roadmap tissue to show similar results . Let peng to use PE's network, compare results? Response 100 C To use the imputed network in tissue and used the KD data in cell line as a validation KD in tissue external data **** we've really made better use of the encode knockdown data and highligh &&&& & knockdowns We thank referee for bringing this point and we feel it is a great comment. Actually, the referee is correct many of the cancer transcriptome is similar to each other and we made a Deleted: (DL maybe) [... [10]] new figure in our revised version. Deleted: As One of the strengths of ENCODE release 3 is massive expansion of functional genomic data into various primary cells and tissue types. In this revision, we have extensively Deleted: stated in the manuscript, we agree with explored the chromatin landscape and expression patterns across all of available ENCODE Deleted: that immortalized cell lines may not be the best primary cells and tissues, and compared with existing immortalized cell lines with deep representation of normal and cancerous counterparts of annotations. We have chosen CTCF ChIP-seq and RNA-seq, which has the most abundant primary cells and tissues. number of cell types in ENCODE, as an example to highlight this point. We looked at Deleted: that ENCODE cell lines are not far different from differential binding patterns of CTCF at promoter regions across cell types. The t-SNE plot primary cells. ...[11] of CTCF network shows that most of normal cell lines form a cluster together with healthy primary cells, and cancer cell lines can be linearly separable from their normal counterparts.

	across tissues of origin. https://www.ncbi.nlm.nih.gov/pubmed/25109877 "Five subtypes were nearly identical to their tissue-of-origin counterparts, but severa distinct cancer types were found to converge into common subtypes." Ref 4.8	- Aspects of heterogeneity related to cell liens
\$\$\$CellLine	e \$\$\$Text @@@WM @@@JZ <mark>@@@MRS</mark> @@@PDM&&&compl
Referee Comment	6) Most cancers are not necessarily represented by a single cell type used to obtain genomics data in this study, but contains numerous types of cells with different mutations, as well as normal cells, infiltrating cells, all in a three

	infiltrates, hormonal factors, normal cell populations, etc.) are significant factors in tumor growth and development. Nonetheless, we feel there remains value in single-cell comparisons between tumor and normal cells.
	Among the strengths of cell-line comparisons is the ability to perform well- controlled analyses of cancel cell function in a way that is not possible with whole tumor specimens. For example, the detailed gene co-expression network analyses we highlight in our manuscript (see section XXX), were made possible by a homogenous cancer-cell population with robust and uniform expression signal. Such an analysis in whole-tumor specimens would be challenging due to the need for deconvolution of expression signals originating from various cell types present in tumors.
	Apart from the advantage of single-cell analyses of enabling examination of complex cancer cell biology, there is, moreover, reason to believe that single-cell analyses may capture important tumor biology present <i>in vivo</i> . Cancers that result from a single progenitor cell, or homogenous progenitor population, provide a justification for the use of single-cell analyses and comparisons. There is evidence that a number of cancers may develop according to the cancer stem-cell model, which posits that it is only a small population of stem-like cells that are responsible for tumor development and observed intratumoral heterogeneity (PMID: 24607403). Understanding the biology of a single cells in the progenitor population may be sufficient to gain perspective on the tumor landscape as a whole.
	Even when there is genomic heterogeneity observed across tumor clones and subclones, the main driver mutations and phenotypic traits may be widely shared among cells (PMID: 3944607, 21376230). For example, in a single-cell sequencing analysis of colon cancer, the primary drivers TP53 and APC were present in the majority of cells across clones, with other mutations showing greater heterogeneity. (PMID: 24699064) Furthermore, even when there is substantial initial genomic and phenotypic heterogeneity, tumors may tend to converge to a genomic and phenotypic equilibrium (e.g, to a stem-like state) as has been shown in a number of studies on breast cancer tumor evolution (PMID: 21854987, 21498687, 22472879).

We agree with the reviewer that the concept of using genomics features can help to estimate BMR. However, our goal in this manuscript is to demonstrate that ENCODE data is quite useful for a variety of models, rather than to develop a novel cancer driver detection method. The BMR part takes only two sub-panels of Fig. 2, and we do have many other aspects in the manuscript to go beyond this point. For example,

1

Comment [11]: good but dangerous

	<ol> <li>We provided accurate noncoding annotation by integrating multiple novel assays such as Hi-C and STARR-seq, which may increase power in somatic mutation burden test.</li> <li>We integrated more than 1000 ChIP-seq/eCLIP experiments to provide detailed TF/RBP networks. By combining cohort RNA-seq data, we identified both known (TP53 and ESR1) and novel (SUB1) cancer-associated regulators</li> <li>Through whole genome sequencing data, we provided high-quality SV calls in top cancer cell lines, and investigate their effects on enhancers and networks.</li> <li>For the first time, we have incorporated thousands of ChIP-seq experiments to directly observe the tumor-to-normal network perturbations and quantify it such changing events</li> </ol>

Referee Comment	1. The manuscript does not clearly state innovation and novelty over previously published data and methods. Several published studies have used epigenomic data types, including replication time and histone modifications from ENCODE and other sources, to model background mutational background density and define genomic elements of interest. The use of the Negative Binomial/gamma-Poisson distributions to model mutational background in cancer has also been published (Imielinski et al 2016; Martincorena et al, 2017).	Formatted Table

Referee Comment	5. "Increased" power of the combined strategy is suggested in. the manuscript, yet comparison to prior work is missing.	Formatted Table
Author Response	We thank for the referee to point this out. In our revised manuscript, we have added a whole new section in the supplementary file to discuss this problem. In summary, previous power calculations was based on the assumption that all functional sites are within the test region, hence it is better to have short and accurate annotations. However, we found that this assumption is pretty strong and is not realistic for some cases. Instead, we added a whole section where some functional sites are allocated across multiple regions and then a combined strategy is better.

#### -- Ref 5.18 – KD in MYC --

1

#### \$\$\$Network \$\$\$Text @@@DC_&&&compl

Referee Comment	13. MYC is known to have profound effects on gene networks. Have the authors considered comparing the results from their MCF7 knockdown experiment to existing data from similar MYC knockdowns to validate the behavior of the network?
Author Response	We thank the referee for this suggestion. We carried out these analyses after first identifying an alternative dataset. Specifically, we identified a dataset of gene expression for both MYC knockdowns (as well as a corresponding control) in Gene Expression Omnibus (GEO accession number GSE86504). For these alternative data, gene expression was measured by RNA-seq in the HT1080 cell line.
	We note that, even though these alternative analyses were conducted on a different cell line, the results we obtain (shown below in the right panels, and now made available in the supplementary materials) validate the behavior of the network, and they are consistent with our previous results (in which gene expression was measured in the MCF7 cell line). These comparable results in an alternative cell line suggests that these results are robust.

Page 4: [1] Deleted	MS	3/11/18 7:01:00 PM
<i>(Core of the argument)</i> It is unique in the following aspects.		
Page 5: [2] Deleted	MS	3/11/18 7:01:00 PM

We disagree with the reviewer with regarding the new dataset and novelty of this manuscript.

# 1. Regarding the separate dataset to the main ENCODE manuscript

First, unlike previous roll-outs, ENCODE 3 does not associate specific data sets with specific papers. In addition, there are no dependencies between any of the papers in this package. All the ENCODE data is open to the public and is not associated with, for instance, the encyclopedia paper or a particular companion paper.

In addition, while the encyclopedia paper considers annotations across cell-types (currently the center-piece of ENCODE), it does not take advantage of the cell lines rich in data. The ENCODEC paper takes a complementary approach by constructing cell-type specific annotations from cell lines rich in assay data. This ENCODEC Paper is unique *in its inclusion of replication timing data, STARR-seq and Hi-C data, rich annotations, and extensive network information*. None of these aspects are discussed in the main ENCODE manuscript.

# 2. Regarding the novelty of the manuscript

In the initial submission, the BMR calculations in the original manuscripts only occupy two sub figures of six total figures, but received the most criticism. We thank the referees pointing out a serie of references on this topic, especially the Martincorena et al 2017 paper. Note that this paper come out in Nov 2017 and we did our submission on Aug 22 2017. There are lots of other important discoveries in the paper as listed below[1]. We also take the comments in heart and did a major revision to expand the novelty part.

# 2a) extensive regulatory networks for various cancer types

In our revised ENCODEC manuscript, we provided a universal TF and RBP regulatory network based on xxx ChIP-seq and eCLIP experiment. Combining with RNA-seq data from TCGA, we proved that our network is more accurate than previous ones based on pure computational predictions.

Using these networks, we prioritized known regulators such as TP53 and ESR1, and used both ENCODE and public TF knockdown datasets as validations. We also pinpointed out a potential novel oncogene SUB1. It serves as a RNA binding protein to bind to the far most of 3' UTRs to up-regulate its target gene expressions. We also found that targets of SUB1 have a slower decay rate, indicating its important roles in regulating stability of mRNAs. In addition to looking at universal (not cell type specific) ChIP-Seq networks, we also look at network changes on a large-scale, tissue-specific manner. We feel that the rewiring of networks is best exemplified in cancer cells.

# 2b) More accurate annotations after integrating new types of assays

Our ENCODEC manuscript takes a complementary approach by constructing cell-type specific annotations from cell lines rich in assay data. These annotations[2] are important in power calculations related to recurrent mutations. This highly accurate annotation takes advantage of next generation assays such as STARR-seq and elements linked by ChIA-PET and Hi-C. This is not possible obviously in the general and co-annotation but it's extremely useful on the cancer context.

# 2c) Replication timing data

Although a major feature of ENCODE is replication timing, none of the other papers use it. Previous work [[cite]] on mutation burden calculation usually selected replication timing data from HeLa cell line due to the limited amount of data available. The wealth of the ENCODE replication timing data will greatly help to parametrize somatic mutation rates. We will highlight this in our revised manuscript.

#### 2d) Structural variations

Page 5: [3] Moved to page 3 (Move #1)	MS	3/11/18 7:01:00 PM

#### One

Page 5: [4] Deleted	MS	3/11/18 7:01:00 PM

unappreciated aspect of ENCODE is that next generation functional assays, in addition to characterizing functional elements in the genome, enable one to determine structural variants. This has been the case for the Hi-C experiments, but there are many other experiments done by experimentalists that have given rise to a large number of structural variants. These structural variations of course are most applicable to the cancer cell lines that many of the ENCODE assays have been run on. We have referenced these structural variations in the earlier version of the paper but admittedly have not really highlighted them or talked about them as much. Since ENCODE provides novel SV data and inclusion of SV analysis was suggested by some of the referees, we have greatly expanded our analysis of SVs in the context of cancer. We will include some new figures as well as add a variety of new data sets that have been designed specifically for this project.

# 2e) TF/RBP knockdown/knockout experiments

ENCODE has 77 CRISPRi based TF knockout and and 533 shRNA based TF/RBP knockdown experiments, which serves a great resource to investigate network perturbations after disruption of a regulator. The ENCODEC paper is the only paper that focuses on such data. In our current manuscript, we have already used some of such knock down data to validate effects of key regulations in multiple cancer types. We will highlight the usage of such experiments in our revised version.

Page 7: [5] Deleted	MS	3/11/18 7:01:00 PM

# ## WM

Certainly, several groups have used epigenetic data before to model gene regulatory networks and background mutation rates. The present work is novel in that it offers substantially wider and deeper integration of diverse, specialized functional assays than does any prior work, including use of the specialized functional assays STARR-seq, Repli-Seq, and eCLIP and an analytically more sophisticated construction of gene regulatory networks.

Our significant findings include the following:

1. Our compact enhancer annotations and extended gene definitions increase our power to detect significantly burdened genes. This would have permitted, for example, the discovery of CANCER_GENE_X with a Y% smaller cohort.

Network-driven estimates of the contributions of all relevant TFs to the expression levels of all cancer genes. For example, we find that TF1 and TF2 most upregulate EGFR expression in lung adenocarcinoma.
 The regulatory network changes from the cell-of-origin to cancer cell bring cancer cells to a more stem-like state.

# ##

However, we disagree with the reviewers regarding the novelty of this paper.

The main focus of our work is to perform large scale data integration in order to tailor the ENCODE resource for cancer research. For example, in our manuscript we showcase the value of ENCODE data in improving BMR to aid in driver mutation detection. As mentioned by the reviewer, an improved cancer driver detection method is an important topic that been the subject of several high profile papers (see, for example, Martincorena, 2017, published 3 months after our submission). Such prior results do not compromise the novelty of our paper and signify the value of our data. Our purpose is not to propose a better cancer driver detection method, but to highlight the value of ENCODE data applied to cancer research.[3]

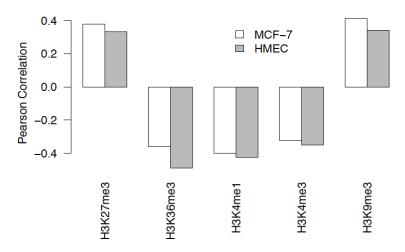

There are many elements of our initial submission that we have been expanded in this revision. These elements are summarized in the section above. As an ENCODE resource paper, we hope the deliverables, including processed raw signal files, a more accurate and more compact genome annotation, and extensive tissue-specific and universal regulatory networks provide value to the cancer community.

Page 12: [6] Deleted         MS         3/11/18 7:01:00 PM	Page 12: [6] Deleted	MS	3/11/18 7:01:00 PM

TP53, ESR1, ZNF687, and SUB1.

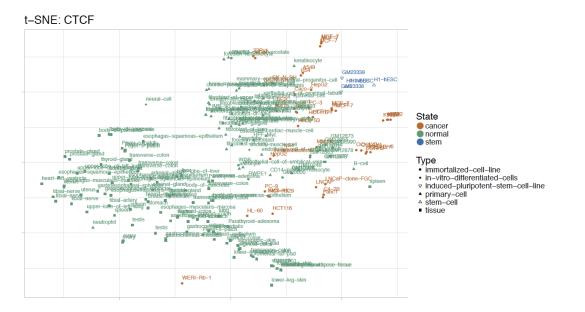

Although we did see PCs used in other literature (Marticorena, 2017). It is mainly for a less computationally intensive feature selection procedure to use on all cancer types. In our analysis, we believe that various cancer types might come from completely different origins. To maximize the BMR estimation accuracy, it is better to use tumor-specific features separately. Hence, we used forward selection in our analysis and in the revised manuscript, we made it very clear.
